ABSTRACT:

An oscillatable nozzle sprinkler with operationally changeable nozzles from the top. One configuration consists of a multiple nozzle cylindrical sleeve which allows a desired nozzle for flow rate and trajectory to be rotationally selected while the sprinkler is operating. Another configuration allows individual nozzles to be inserted into the top of the sprinkler housing while the sprinkler is operating.

Number of Drawing Sheets: 3

BRIEF SUMMARY:

DESCRIPTION

1. Technical Field

This invention relates to oscillatable sprinklers with multiple nozzles of different flow rates and discharge trajectories that can be selectably changed when the sprinkler is installed and operating.

2. Background Art

In U.S. Pat. No. 5,098,021 an integrated system is set forth for varying the flow rate of a single nozzle to meet precipitation rate requirements for varying arcs of oscillating coverage. No provision is provided to correct the flow rate of the nozzle for varying ranges when using a nozzle stream break-up screw to limit the nozzle range.

U.S. Pat. No. 5,104,045 relates to sprinkler nozzles having flow passages for obtaining desired precipitation coverage. This patent shows how nozzles are typically installed and retained in oscillating sprinkler nozzle housings.

U.S. Pat. No. 4,867,378 shows a sprinkler device for directing a flow of water therefrom having a single nozzle in a nozzle housing assembly, said sprinkler having an output drive shaft.

Other sprinklers in the market place have separate nozzles of different flow rates or trajectories but can only be installed into the sprinkler nozzle housing when the sprinkler is not operating. In order to change to a new desired nozzle the undesired nozzle which was installed in the sprinkler's nozzle housing must also be removed before the new desired replacement nozzle can be installed.

DISCLOSURE OF INVENTION

It is an object of this invention to make it possible to select a nozzle for the desired range and flow rate to provide the desired precipitation rate while the sprinkler is operating. This is accomplished by molding or inserting various nozzles around the circumference of a cylinder which is rotationally mounted on the nozzle housing. The desired nozzle can be rotated into the flow path while the sprinkler is operating if it is desired to change the range and/or flow rate of the sprinkler. After installation if it is found that a local area of the yard needs more or less water from that of the other sprinklers running in that irrigation zone it is only necessary to rotate the multiple nozzle selection sleeve, or cylinder, to a different flow rate or trajectory nozzle as indicated around the top circumference of the nozzle selection sleeve to provide an increased or decreased precipitation for this area of the yard.

Also, the sprinkler may be shut off at the sprinkler by turning the nozzle selection cylinder to a blank rotational location indicated as off.

An alternate configuration is also shown which also allows the nozzle to be changed during operation from the top and behind the stream, but has the disadvantage that the other nozzles must be carried separately and are not present on the sprinkler at all times and immediately available after installation.

This concept makes it simple to locally increase or decrease the sprinklers flow rate to better match the precipitation to varying soil or sun light conditions after the installation has been completed and the landscaping has stabilized.

Optimum water usage can thus be more easily achieved. The easy removal of the nozzle selection sleeve also makes cleaning of dirt or debris from the nozzle easy compared to other sprinklers now on the market and can be done without having to shut the system off and then turned back on after the nozzle has been cleaned.

#### DRAWING DESCRIPTION:

##### BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a fragmentary sectional side view of a rotatable sprinkler nozzle housing assembly being driven by an output shaft and showing the rotationally mounted multiple nozzle selection sleeve.

FIG. 2 is a top view of the nozzle housing assembly showing the nozzle identification around the top circumference of the nozzle selection sleeve. Also the removal slot and retention lug can be seen for retaining or allowing removal of the nozzle selection sleeve from the nozzle housing assembly.

FIG. 3 is a fragmentary sectional side view of a rotatable sprinkler nozzle housing assembly showing a nozzle insert plate removable and insertable from the top.

FIG. 4 is a top view with a cut away of the nozzle housing assembly showing the removable nozzle insert plate in position.

FIG. 5 shows the multiple nozzle selection sleeve removed from the nozzle housing.

FIG. 6 shows a nozzle insert plate.

#### DETAILED DESCRIPTION:

##### BEST MODE FOR CARRYING OUT INVENTION

Referring to FIG. 1 and FIG. 2 of the drawings, a rotatable nozzle sprinkler is shown having a cylindrical nozzle housing assembly 1 mounted for rotation about axis x--x on the top of a riser assembly 2. The riser assembly has a center shaft opening at its upper end for the nozzle housing assembly drive shaft 5 to exit the riser assembly 2 and be connected to the nozzle housing assembly 1.

The nozzle drive shaft 5 is hollow and water is supplied to the nozzle housing 16 through the hollow center passage of the nozzle drive shaft 5 into a flow passage 15 in the nozzle housing 16. Water enters the riser assembly 2 at its lower end and is used to power a rotary drive mechanism for turning the nozzle drive shaft 5 before exiting the riser assembly through the hollow center passage of the nozzle drive shaft 5.

The nozzle housing 16 flow passage 15 extends through the nozzle housing 16 to the outside of the nozzle housing at an upward angle. The constructions of a nozzle housing with a flow passage is shown in U.S. Pat. No. 5,098,021 and U.S. Pat. No. 5,104,045.

The flow passage 15 in the nozzle housing does not determine the sprinkler's stream trajectory for this design. A separate nozzle selection cylindrical sleeve 40 which is rotationally mounted on the nozzle housing 16 has multiple individual nozzles 42 molded into the sleeve wall 44. Each nozzle can be separately configured to give a desired trajectory angle and sized to provide a desired flow

CLAIM - AS A RESULT OF REEXAMINATION, IT HAS BEEN DETERMINED THAT: The  
patentability of claims 12-15 is confirmed. Claim 3 is cancelled.  
Claims 1, 4-11, 16 and 18 are to be patentable as amended. Claims 2,  
17 and 19, dependent on an amended claims are determined to be  
patentable. New claims 20 and 21 are added and determined to be  
patentable. 1. A aprinkler (having) comprising: a rotatable nozzle  
housing having a water passage formed therein; an output shaft  
mechanically connected to said rotatable nozzle housing for rotating  
said nozzle housing(,); a manually adjustable rotatable sleeve having  
an inner surface and a plurality of circumferentially spaced  
(orifices;) nozzles, each of said nozzles having mutually different  
configurations from each other, said rotatable sleeve (is) being  
slidably installed around the nozzle housing and being in rotational  
relationship therewith and thereto so that said rotatable sleeve can  
be selectively positioned to align one of said plurality of nozzles  
with the discharge end of the water passage for distributing water  
outwardly from said sprinkler; sealing means surrounding the discharge  
end of (a) the water passage formed in said nozzle housing (;), said  
sealing means including a seal member surrounding the discharge end of  
the water passage and dimensioned to continuously bear against said  
inner surface of said rotatable sleeve to provide a sealed connection  
to the pressurized water passage of the nozzle housing (, wherein said  
rotatable sleeve is selectively positioned to align one of said  
plurality of orifices with said discharge end of the water passage for  
distributing water outwardly from said sprinkler,); and means for  
retaining said (nozzle selection) rotatable sleeve in place.
